AGENCIES, SYSTEMS, IDENTIFIERS, AND EVENTS — NOT A REAL
FILING OR CYBERSECURITY GUIDE**

Declaration on Repositories, Search Terms, and Deduplication

Filed: August 4, 2025 **Synthetic docket:** SYN-DMD-25-CV-0914 **Search log:** SRCH-OG-2025-0804

I, Dalen Saye, am the fictional search-and-deduplication specialist assigned to ORER. I designed and documented the collection method for DOE-FOIA-2024-OG-041 after the June 21 clarification. My statements are based on the synthetic search log, export manifests, deduplication report, and custodian disposition sheet.

The objective was to locate authoritative final or superseded Grid Sentinel editions effective from January 1, 2022, through May 31, 2024, plus unique final approval and supersession records. The method excluded the categories that Open Grid removed from scope. It did not scan a live environment, collect telemetry, or evaluate a real cyber event.

I used automated retrieval to assemble candidates, content and metadata comparison to reduce duplicates, and human custodian review to decide finality and responsiveness. No single keyword was treated as conclusive. The stages and figures in this declaration are reproducible within the fictional repository exports.

The search produced twelve responsive records containing 200 logical pages. That count reflects authoritative source items, not later public and sealed litigation copies.

Locations Selected

Beacon is the fictional library for approved final policy records. It stores an authoritative content object with title, version, effective date, approval status, and controlled family terms. It was reasonably likely to contain current editions and approved exercise material.

Driftglass is the invented archive for superseded versions. Its fields preserve prior content, supersession date, and the identifier of a replacement. It was chosen because the request included editions effective earlier in the period. The archive does not represent a backup of live systems.

Harborline is the synthetic correspondence store used for final records instruments. Search access was limited to items designated as a final approval memorandum, final supersession notice, or final distribution log. Routine email, invitations, comments, and draft transmittals were excluded under the clarification.

Ari Tern and Milo Crest confirmed that these three locations covered the record families. Kira Morrow confirmed that no other ordinary repository was reasonably likely to contain an authoritative final edition. I documented those confirmations before export. We did not search personal devices or unrelated component files because the agreed scope and custodian information did not indicate responsive authoritative records there.

Terms and Field Logic

The collection combined the phrase “Grid Sentinel” with the controlled family terms “Operational Decision Tree,” “Cyber-Incident Escalation Matrix,” and “Response-Coordination Appendix.” Governance retrieval also used “revision approval” and “supersession.” Searches included common punctuation and spacing variants recorded in the repository indexes.

Field conditions required an approved or final status and an effective period overlapping the agreed range. For Driftglass, an edition approved earlier could qualify if its supersession date fell on or after January 1, 2022. An item approved after May 31, 2024, did not qualify merely because its description mentioned an earlier version.

I also queried version and replacement relationships to find a record indexed primarily under its family name. This avoided reliance on the suite name alone. Harborline results had to carry a final-instrument designation; a message containing the same words but lacking that status remained outside the collected governance subset.

The query did not include vulnerability, credential, live address, or incident terms. Those subjects were excluded, and adding them would have expanded rather than improved the agreed search. Candidate retrieval ended June 30, with export packaging finished July 2.

Raw Results and Duplicate Reduction

The three exports contained 16,842 raw hits. Many were replicated index entries, distributed copies, format variants, or references to the same approved content. I first normalized repository-generated wrappers without changing the document body. I then compared exact content digests and approved metadata fields.

Exact duplicates were collapsed to one candidate linked to its authoritative location. Near duplicates were not automatically discarded. If two files differed in body text, version, approval state, or effective date, both remained for custodian review. A format-only conversion with identical readable content was associated with the same candidate but retained in the audit log.

That process yielded 1,284 distinct candidate files. Automated status and date filtering identified ninety-three items requiring a closer metadata check. I examined conflicting labels and referred ambiguous finality questions to the custodians. Forty-six candidates survived to substantive custodian review.

The deduplication log records the count removed at each step and the reason code. It does not preserve or expose any excluded operational data. A reviewer can reconstruct the numerical path from raw hits to candidates without opening a real system or learning a protected playbook value.

Custodian Review and Responsive Set

Kira Morrow and the designated records liaison reviewed the forty-six candidates. They applied the clarified effective-date, finality, record-family, and correspondence rules. Twenty-one candidates were drafts or unapproved working material. Eight were nonauthoritative transmittal copies whose content matched a retained item. Five were routine messages or references rather than a final instrument.

The remaining twelve candidates were responsive authoritative records. Four belong to the decision-tree family, three to the escalation-matrix family, three to the coordination-appendix family, and two to governance. Their page subtotals are sixty, fifty-four, sixty-four, and twenty-two, respectively.

I compared the sum of individual file page counts with the 200-page total. I also confirmed that a record appearing in more than one repository relationship was counted once. The custodian disposition sheet assigns a reason to every one of the forty-six reviewed candidates, so the twelve responsive selections are not inferred solely from the final production.

The search process did not determine which responsive content was exempt. After the set was fixed, Elian Voss coordinated a separate substantive review. My role in that later stage was limited to maintaining record identifiers and source-page counts.

Quality Controls and Search Adequacy

I ran a reverse check from the final version chain. For each current family record, I followed its fictional predecessor field through Driftglass until the chain moved outside the date boundary. I compared that list with the candidate set. Every qualifying approved edition had been collected.

I separately checked the approval identifiers attached to the retained editions against Harborline's final-instrument index. The comparison located the two unique governance records already selected and no additional final memorandum. I sampled discarded exact-duplicate groups to confirm that the retained authoritative copy contained the same readable body.

Search terms were also tested without the Grid Sentinel suite phrase. Family-only retrieval found records already present in the result set and did not identify an omitted authoritative edition. Custodians certified that the invented repositories covered their ordinary recordkeeping locations.

These controls led me to conclude that the search was reasonably calculated to locate records within the agreed scope. The conclusion is limited to that scope. It says nothing about excluded incident files, drafts, or live technical information, none of which was sought. If another responsive authoritative record were later identified, the search log would record and route it rather than treat this declaration as a bar to correction.

Declaration and Preservation of the Search Record

Search log SRCH-OG-2025-0804 contains the query descriptions, export dates, numerical stage totals, deduplication reasons, custodian routing list, and quality-control results. It stores no credential and provides no access path to a repository. The log was preserved with the administrative FOIA file after the October 7 appeal decision.

I verified the central arithmetic before execution: 16,842 raw hits; 1,284 deduplicated candidates; forty-six custodian-reviewed files; twelve responsive records; and 200 logical source pages. I further verified that the responsive family counts are four, three, three, and two. Nothing in a later court-filed twin changes those source totals.

All named systems and personnel in this declaration are fictional. Beacon, Driftglass, and Harborline are descriptive exercise constructs. No statement should be understood as revealing an actual DOE records architecture.

I declare under penalty of perjury that these facts are true and correct within the synthetic record. Executed on August 4, 2025.
