

Supplemental Declaration on Re-Search and Segregability Review

Filed: September 8, 2025 **Synthetic docket:** SYN-DMD-25-CV-0914 **Supplemental
production:** RLS-OG-002

I, Elian Voss, provide this supplemental declaration after reviewing the issues raised in the pleadings and early litigation submissions. I repeated targeted search checks, coordinated another review of withheld passages, and prepared a supplemental public index with a sealed inert counterpart.

The second review released seventeen text passages spread across eleven page images. Those passages consist of administrative headings, revision language, general coordination prose, and document-control statements that reviewers concluded could be read without exposing an assigned operational relationship.

Targeted Re-Search

Dalen Saye reran the family-only and suite-name queries against frozen exports from Beacon, Driftglass, and Harborline. The effective-date and finality conditions remained those accepted on June 21, 2024. We also searched the predecessor and replacement fields for each of the twelve retained records and cross-checked the two governance instruments.

The re-search returned no new authoritative final edition. Results not already associated with the twelve records were duplicates, drafts, routine transmittals, or outside the operative date range. Because the exports were preserved at processing, the check tested the original search universe without reaching into a live or unrelated environment.

I asked Ari Tern and Milo Crest whether an additional ordinary records location had been identified since their earlier certifications. Each answered no. Kira Morrow confirmed that the final version chains remained complete. These responses were added to the synthetic search log.

I therefore maintain the adequacy conclusion described in the original declarations. The supplemental work focuses chiefly on segregability and specificity, not a changed collection. The responsive arithmetic remains four decision-tree records, three matrices, three appendices, and two governance records.

Renewed Segregability Method

For the second review, each withheld segment was assigned one of four treatment questions. First, can the passage be understood as administrative text without a protected value? Second, would its location reveal the order or relationship of two protected fields? Third, is the passage a general heading that remains meaningful after subordinate detail is removed? Fourth, does a claimed 7(F) field contain a harmless descriptor separable from the value beneath it?

Reviewers compared public and sealed working copies but recorded the decision through stable semantic segments. They did not place a raw sealed citation in the public worksheet. A proposed release was read with the preceding and following visible text to determine whether context itself would reconstruct an assigned condition or sequence.

The team reconsidered all fifty-four fully withheld pages and each blackout on the seventy-eight redacted images. A no-release result was accepted when the reviewer stated that the remaining words would be meaningless or would expose the protected relationship. A release result required exact text selection and a confirmation that no inert sealed value would appear.

The method produced seventeen additional passages on eleven already-produced pages. It did not turn any fully withheld record into a partial release.

Supplemental Release Accounting

RLS-OG-002 supplies replacement images for eleven pages. Six pages contain two newly visible passages each, while five pages contain one each, yielding seventeen passages. The replacement images retain all previously visible text and narrow selected blackouts; they do not alter pagination.

Four released passages are document-control statements identifying revision ownership or review status. Three are neutral section headings. Six are general coordination sentences that do not identify a fictional role value or branch. Four describe recordkeeping or closure without revealing an operational sequence. None contains a contact channel, safety placement, decision value, or implementation order.

The eleven images belong to five of the seven partially released records: GS-DT-T1, GS-DT-QA, GS-EM-T1, GS-CA-4.2, and GS-CA-3.7. No new passage was released from GS-EM-3.7 or GS-CA-T1 after contextual review. The two fully released governance records required no replacement.

Because these are revised images of pages already within the 146-page production, the produced-image count remains 146. Describing the passages does not revise the source-page disposition totals used in the initial decision.

Updated 7(E) Descriptions

The supplemental index separates condition values, response ordering, implementation relationships, and guideline branches rather than describing all 7(E) material as operational logic. It links each functional description to a record and page segment. This added specificity remains abstract; no value, sequence, or actionable step is disclosed publicly.

For a technique or procedure, the asserted concern is that the nonpublic arrangement itself would become known. For a guideline field, the review additionally records a prediction that exposing the fictional condition or branch would allow anticipation of when the framework changes classification. Current and superseded records are described separately where comparison creates the asserted inference.

Reviewers removed several administrative passages from the 7(E) category after determining that they did not reveal an arrangement. The seventeen-text release includes material formerly adjacent to operational content. We nevertheless maintain that the remaining identified condition and ordering segments are protected.

The sealed counterpart substitutes harmless labels for public notices so the Court can see the field distinction. Condition-Aster and Sequence-Beryl are invented markers, not actual condition content or a usable ordered procedure.

Updated 7(F) and Harm Descriptions

The supplemental review retains the four functional 7(F) labels used previously: duty role, contact channel, safety reference, and escalation position. The index now states which label appears in each record segment and whether 7(E) overlaps. It does not name any actual person or place.

ORER continues to predict that exposing those fields could facilitate interference with people performing protective functions in the hypothetical. The sealed copy shows inert values—Role-Dovetail, Channel-Fable, Safety-Echo, and Value-Cinder—so reviewers can distinguish field types without receiving an operational fact. The public copy substitutes category-specific notices.

The team released neutral headings and coordination prose when it concluded that they did not identify a field value. It retained other descriptors when context was viewed as revealing a safety-related assignment. The rationale remains common to each functional label rather than stating a unique threat narrative for every blackout.

I understand that Open Grid maintains its challenge to the causal specificity of this showing. The supplemental description records the agency's renewed position and the evidence it supplies. It does not assert that labeling a field automatically resolves the legal standard.

Revised Segregability Conclusion

After the additional release, I again conclude for ORER that no further reasonably segregable nonexempt information has been identified. The conclusion rests on the segment worksheet, contextual review, and custodian confirmation. It is narrower than the initial statement because seventeen passages once withheld are now visible.

For the three fully withheld records, the team continued to find the protected relationships distributed through the operational organization. For the seven partial records, reviewers retained only segments they believed would reveal a condition, ordering relationship, guideline branch, or safety-related field when read in context. The public supplemental index states those reasons by functional segment.

The review considered foreseeable harm separately. A 7(E) segment required a prediction involving reconstruction or anticipation of the framework. A 7(F) segment required a prediction involving interference with a protective human function. Where both applied, both were recorded.

The revised conclusion does not depend on how many pages were produced. It depends on the team's assessment of the remaining text. The Court may determine whether the evidence is sufficiently detailed; my role is to describe the process accurately.

Declaration

I reviewed RLS-OG-002, the eleven replacement images, the seventeen-passage log, the renewed search report, and both supplemental indexes. The public and sealed index counterparts contain seven corresponding logical pages. Their semantic segments align even though public prose is independently worded and sensitive fields appear only as notices.

The re-search and reprocessing did not alter the twelve-record, 200-page responsive universe. No new record was found, and no page moved among the three whole-record disposition categories. The electronic production remains 146 images, eleven of which now contain additional text.

Every name, repository, value, and response concept in these materials is synthetic. The sealed markers are inert and cannot guide an actual cyber action. I have not included a real address, credential, protocol, vulnerability, or facility characteristic.

I declare under penalty of perjury that the foregoing is true and correct within this fictional case. Executed September 8, 2025.
